ACC NR: AP6002591

effectiveness of gathering the debris on the surface of the water and for discharging the debris on shore. The gathering-transport unit is made in the form of a reversible conveyor with a water-permeable mesh conveyor belt. The conveyor is attached to the barge by hinge-swivel arms which hold the conveyor at an inclined position in respect to the surface of the water for gathering of the debris. The arms also lift the conveyor to an inclined position in relation to the shore for discharging of the debris. To mechanize the contents of the bunker, the take-away carriage is connected by a cable to a reversible winch. Orig. art. has: 1 figure.

PERIODICAL: Sb. tr. In-ta stroit. mekhan. AN UkrSSR, 1956, Nr 21, pp 103-114

ABSTRACT: The nature of the problem of determining the long-time rupture-strength properties of wood is examined, and means therefor are discussed. The choice of the time reference base to be used in testing to determine these properties is substantiated, and a method is propounded for estimating them (in a multiple-stress condition) from data obtained from tensile and compression tests. Experimental verification of the method's workability is described for a case of pure bending. Experimental rupture-strength curves are given for pine, oak, and beech (tested for tension, compression, cleavage strength along the grain, and pure bending).

TITLE: The Bending of Wooden Beams With Due Allowance for Plastic Deformations (Izgib derevyannykh balok s uchetom plasticheskikh deformatsiy)

PERIODICAL: Sb. tr. In-ta stroit. mekhan. AN UkrSSR, 1956, Nr 21, pp 119-133

ABSTRACT: The article is based on universally adopted hypotheses. An equation is derived permitting the determination of the Bach coefficients for beams of arbitrary cross section as well as for the particular case of beams of rectangular, circular, semicircular, I-shaped, and box-shaped cross sections. Compared with existing solutions, the formulas for the last four types of sections are found to be more accurate. It is pointed out that for beams of any cross section having at least one axis of symmetry the relationship between the Bach coefficient and the values of the ratio of the ultimate tensile to the ultimate compressive strength along the fibers is always expressed in the form of a hyperbolic function. In addition to determining the Bach coefficient, the author presents formulas for all the types of beams examined

Card 1/2

The Bending of Wooden Beams With Due Allowance for Plastic Deformations

above; with the aid of these formulas the ultimate bending moment and geometric characteristics of the cross section of a beam operating in the elastic-plastic region can be determined. It is pointed out that, depending on geometrical characteristics of the section and the strength characterisitics of the material of I-beams and box-beams, three different design cases are possible.

PURPOSE: This book is intended for use in laboratories in the testing of construction and machine-building materials. It may also be useful to engineers working in organizations concerned with structural design.

Card 1/6

Deformability and Strength of Wood as an Elastic, Ductile and Plastic Substance 260

COVERAGE: Results are given of a study of the laws of deformation development and of the strength of resilient, ductile, plastic bodies subjected to external forces over a period of time. The results of an investigation into the effects on a body of a prolonged constant load are studied experimentally and theoretically developed. On the basis of the study of deformation development and of the strength of materials under a prolonged constant load, formulae are derived for the determination of the basic mechanical characteristics of materials subjected to forces for short periods in machine testing with given loading speed and given rate of deformation. There are 28 references,26 of which are Soviet and 2 English.

TITLE: An Accelerated Method for Determination of the Durable Resistance Limit of Wood (Uskorennyy metod opredeleniya predela dolgovremennogo soprotivleniya drevesiny)

PERIODICAL: Dopovidi Akademii Nauk Ukrains'koi RSR, 1958, # 1, pp 33-36 (USSR)

ABSTRACT: On the basis of the theory of strength and deformability of wood as an elastic-tough-plastic solid, the author developed an accelerated method for determining the durable resistance limit of wood. It takes a minimum of time to carry out an investigation by this method, and ordinary testing machines can be used for this purpose. The method proposed is based on the following two assumptions:

1. There is a linear relation between the critical stress, which gives rise to plastic deformations at a permanently operating load, and the rate of increase of the plastic deformation. This relation was repeatedly confirmed by experiments, and it serves also as a basis for the Belyankin accelerated method (used in the Institute of Construction Mechanics of the Ukrainian Academy of Sciences).

2. The critical rate of the increase of elastic deforma-

Card 1/2

An Accelerated Method for Determination of the Durable Resistance Limit of Wood

tions corresponds to the critical stress.

Using these assumptions, it is possible to determine a dependence between the critical stress and the critical rate of elastic deformation increase, from the tests on machines. This method makes it possible to determine the limit of durable strength during one or two hours. The method was experimentally checked and compared with the method of the Institute of Construction Mechanics. A graph, pictured in Figure 3, shows that the results of both of these methods are in satisfactory agreement.

The article contains 3 graphs and 4 Russian references.

PERIODICAL: Dopovidi Akademii nauk Ukrains'koi RSR, 1959, Nr 1, pp 26-28 (USSR)

ABSTRACT: A quick method of determining the long-duration modulus of elasticity of elastic-viscous-plastic materials (like wood or plastics) is suggested, requiring only a few hours of work instead of a month or longer, as required by the conventional methods, and permitting the determination of the instantaneous modulus of elasticity as well. The method consists in the use of linear relation between the critical stress, during machine testing, and the critical elastic deformation, as well as the relation between the critical stress

TITLE: Effects of the Dimensions of the Sample on the Compressive Strength of DSP Plastic

PERIODICAL: Dopovodi Akademii Nauk Ukrains'koi RSR, 1959, Nr 6, pp 615-619 (USSR)

ABSTRACT: The authors studied the effect of the scale factor on the compressive strength of DSP plastic. Since the loading rate affects the ultimate strength, a testing method was adopted which allowed the rate of stress increase to remain constant for all dimensions of the samples with a varying rate of loading. DSP plastic is used by the industry in power constructions (in bearings and other important components) as a substitute for expensive non-ferrous metals and alloys. Depending on the technology employed in their preparation, DSP plastics are subdivided into three categories: a) DSP-B, in which every 10 - 20 layers of thin birch sheets with parallel filaments are superimposed by a layer of sheets with filaments crossing the filaments of the below layer at

Card 1/3

Effects of the Dimensions of the Sample on the Compressive Strength of DSP Plastic

90°. b) DSP-V, in which the layers of sheets criss-cross one another through the whole thickness of the plastic. c) DSP-G, in which the direction of filaments changes within the plastic thickness every 30°. As a construction material, DSP plastic in the majority of instances is subjected to compression. GOST 5704-51 requires that a test compression be made on 15 x 15 x 15 mm samples, under a permanent compression speed of V_p = 4500 kg per minute. At that, the rate of stress increase is 2000 kg/cm^2 per minute. All samples subjected to testing had a 6.3 humidity. The authors tested 10 - 30 samples of every category of DSP plastic, having cross sections ranging from 1.4 to 25 cm^2. Tests were performed on hydraulic "Baldwin" machines, with pressing capacities of 30, 100 and 300 tons. About 600 samples were tested. The results are compiled in 4 graphs and 1 table. It was established that a change in the sample area of about 18 times has practically no effect on the ultimate compressive strength of DSP plastic.

TITLE: Mechanical strength and deformability of plastics as elastic-viscous-plastic bodies under long-term action of constant load

SOURCE: Plastmassy v machinostroyenii i priborostroyenii. Pervaya resp. nauch.-tekh. konfer. po vopr. prim. plastmass v mashinostr. i priborostr., Kiev, 1959. Kiev, Gostekhizdat, 1961, 206-226

TEXT: This is a report of investigations into strenth and deformability of plastics taking into account time as one of the basic factors involved. Although the results do not characterize the great diversity of known plastics, they may be applied to certain groups of laminated plastics (textilite, glass-reinforced plastics, paper-base laminated plastics, etc.). The analysis of the experimental data

Card 1/2

I007/I207

Mechanical strength and deformability...

establishes common laws governing variation of strength and deformability under constant load with due consideration of the time factor. Description of these experiments is given and formulas are derived for calculation of the development rate for plastic deformations and elastic deformations of stress-relieving, of the relationships between critical stress and loading rate, and also between ultimate strength and loading rate. From the experimental data it results that long-term characteristics may be determined from short-term tests. There are 7 figures.

AUTHOR: Yatsenko, V. F. (Kyyiv)

TITLE: Elements of the theory of bending of viscoelastic-plastic rods

PERIODICAL: Prykladna mekhanika, v. 8, no. 1, 1962, 63-70

TEXT: Creep and relaxation of viscoelastic-plastic materials under bending are discussed. In the case of laminar plastics (DSP), glass plastics, cellulose, etc., the maximum strength limit σ_1, the critical stress σ_c and the long-life endurance limit σ_e have larger values under elongation than under compression; this has as a consequence that under bending the deformations develop differently in time (as a function of the magnitude of the bending moment). In the case of bending by a constant load, four different types of deformation may arise: a) The stress applied to the (external) compressed fiber is smaller than or equal to the long-life endurance limit under compression, and the stress applied to the (external) elongated fiber is smaller than the long-life edurance limit under elongation. In this case, only elastic and viscoelas-

Card 1/4

Elements of the theory ...

tic strains develop in the compression and elongation zones of the rod; the elastic strains develop during an infinitely long period of time, but do not lead to fracture of the rod. b) The stress applied to the compressed fiber is larger than the long-life endurance limit under compression, whereas the stress of the elongated fiber is smaller than the endurance limit. In this case, elastic and viscoelastic strains develop in the compression and elongation zones, as well as plastic strains in the compression zone. Notwithstanding the plastic strains, no fracture of the material occurs. c) Both the stress applied to the compressed fiber and that to the elongated fiber are larger than the corresponding long-life endurance limits. In this case, elastic buckling develops first (in the compression zone), followed by viscoelastic which develops during a critical interval (the first critical interval of time), followed in turn by viscoelastic-plastic buckling; the latter develops until the moment when plastic strains arise in the elongation zone; hence their duration (the second critical interval) depends on the critical interval of viscoelastic-strain development in the elongation zone. After the development of viscoelastic-plastic buckling

Elements of the theory ...

the ensuing plastic buckling leads to fracture of the material. The corresponding conditions are formulated, connecting the stresses σ, bending moments M and buckling f. It is noted that plastic strains may arise first in the elongation zone and then in the compression zone. d) If the material is mostly concentrated in the compression zone, fracture may occur even without the development of plastic strains in that zone. In this case, buckling develops during a single critical interval of time. The conditions are set up for stress relaxation. Proceeding from the connection between creep and relaxation, four cases of stress relaxation may occur. Depending on the magnitude of the given axial strain, the relaxation may either lead to fracture or not. In the first case, the relaxation is due to viscoelastic strains only. In the second case, plastic strains arise in the compression zone. No fracture takes place in the first 2 cases. In the 3rd case, fracture occurs as a result of the development of elastic and plastic stresses in both zones; this case is characterized by 2 critical time-intervals. In the 4th case, fracture occurs. These 4 cases of relaxation correspond to the above 4 cases of creep. The results of the investigation permit

Card 3/4

Elements of the theory ...

developing a theory of bending of viscoelastic-plastic rods, allowance being made for the time factor, proceeding from the basic parameters of such materials under compression and elongation. There are 5 Soviet-bloc references.

TITLE: Higher n-Paraffins of Bitkovsk and Dolinsk Petroleum

PERIODICAL: Khimiya i tekhnologiya topliv i masel, 1960, Nr 3, pp 1-5 (USSR)

ABSTRACT: The higher n-paraffins of Bitkovsk and Dolinsk petroleum were studied by complex formation and chromatography on carbon. The study consisted of the following steps: Removal of gasoline fraction; precipitation of asphaltenes with a 20-fold amount of petroleum ether; removal of tars by chromatography on silica gel; and step-wise treatment of the obtained paraffin oil with urea. The amount of urea varied with each successive treatment, and it was 1:1; 2:1; 3:1 and 4:1, based on the starting oil fraction. Methanol (20% based on urea) was used as an activator, and chloroform as diluent and washing liquid. The complex formation was done at room temperature. Since the separation of n-paraffins is accompanied by the formation of complexes with other hydrocarbons, the obtained solid paraffins were subjected with repeated treatment with urea followed by dissolving in chloroform. The amount of chloroform was 8.3:1 based on starting

Card 1/5

Higher n-Paraffins of Bitkovsk and Dolinsk Petroleum

SOV/65-60-3-1/19

paraffin oil sample and it was increased by 10% with each successive dissolving. This treatment with urea and chloroform was continued till the mp of the paraffin fraction was constant. The authors succeeded in separating 4 fractions of n-paraffins from each of Bitkovsk (17 ,12%) and Dolinsk (20, 12%) petroleum. The chromatography on carbon of these paraffins yielded 200 narrow paraffin fractions. Petroleum ether and benzene were used as eluents. The results are given in Table. The structure of obtained paraffins was confirmed by infrared spectra. There are 2 figures; 1 table; and 10 references, 8 Soviet, 1 German, 1 U.S. The U.S. re reference is: Swerh D., Ind. Eng. Chem., 47, 2, 215, 1955.
